Cloudera Runtime HBase Shell overview

### **HBase Shell overview**

You can use the HBase Shell from the command line interface to communicate with HBase.

In CDP, you need to SSH into an HBase node before you can use the HBase Shell. For example, to SSH into an HBase node with the IP address 10.10.10.10, you must use the command:

```
ssh < USERNAME > @10.10.10.10
```

**Note:** You must use your IPA password for authentication.

After you have started HBase, you can access the database in an interactive way by using the HBase Shell, which is a command interpreter for HBase which is written in Ruby. Always run HBase administrative commands such as the HBase Shell, hbck, or bulk-load commands as the HBase user (typically hbase).

```
hbase shell
```

You can use the following commands to get started with the HBase shell:

- To get help and to see all available commands, use the help command.
- To get help on a specific command, use help "command". For example:

```
hbase> help "create"
```

To remove an attribute from a table or column family or reset it to its default value, set its value to nil. For
example, use the following command to remove the KEEP\_DELETED\_CELLS attribute from the f1 column of
the users table:

```
hbase> alter 'users', { NAME => 'f1', KEEP_DELETED_CELLS => nil }
```

• To exit the HBase Shell, type quit.

# Virtual machine options for HBase Shell

You can set variables for the virtual machine running HBase Shell, by using the HBASE\_SHELL\_OPTS environment variable. This example sets several options in the virtual machine.

This example sets several options in the virtual machine.

```
$ HBASE_SHELL_OPTS="-verbose:gc -XX:+PrintGCApplicationStoppedTime -XX:+Prin
tGCDateStamps
    -XX:+PrintGCDetails -Xloggc:$HBASE_HOME/logs/gc-hbase.log" ./bin/hbase
shell
```

# Script with HBase Shell

You can use HBase shell in your scripts. You can also write Ruby scripts for use with HBase Shell. Example Ruby scripts are included in the hbase-examples/src/main/ruby/ directory.

The non-interactive mode allows you to use HBase Shell in scripts, and allow the script to access the exit status of the HBase Shell commands. To invoke non-interactive mode, use the -n or --non-interactive switch. This small example script shows how to use HBase Shell in a Bash script.

```
#!/bin/bash
echo 'list' | hbase shell -n
status=$?
if [$status -ne 0]; then
  echo "The command may have failed."
fi
```

Successful HBase Shell commands return an exit status of 0. However, an exit status other than 0 does not necessarily indicate a failure, but should be interpreted as unknown. For example, a command may succeed, but while waiting for the response, the client may lose connectivity. In that case, the client has no way to know the outcome of the command. In the case of a non-zero exit status, your script should check to be sure the command actually failed before taking further action.

You can use the get\_splits command, which returns the split points for a given table:

```
hbase> get_splits 't2'
Total number of splits = 5

=> ["", "10", "20", "30", "40"]
```

### **Use HBase command-line utilities**

Besides the HBase Shell, HBase includes several other command-line utilities, which are available in the hbase/bin/directory of each HBase host. This topic provides basic usage instructions for the most commonly used utilities.

### **PerformanceEvaluation**

The PerformanceEvaluation utility allows you to run several preconfigured tests on your cluster and reports its performance. To run the PerformanceEvaluation tool, use the bin/hbase pecommand.

```
$ hbase pe
Usage: java org.apache.hadoop.hbase.PerformanceEvaluation \
  <OPTIONS> [-Dproperty=value>]* <command> <nclients>
Options:
                 Run multiple clients using threads (rather than use mapred
nomapred
uce)
 rows
                 Rows each client runs. Default: One million
                 Total size in GiB. Mutually exclusive with --rows. Default:
 size
 1.0.
 sampleRate
                 Execute test on a sample of total rows. Only supported by r
andomRead.
                 Default: 1.0
traceRate
                 Enable HTrace spans. Initiate tracing every N rows. Defaul
t: 0
                 Alternate table name. Default: 'TestTable'
 table
multiGet
                 If >0, when doing RandomRead, perform multiple gets instead
 of single
                 gets.
                 Default: 0
 compress
                 Compression type to use (GZ, LZO, ...). Default: 'NONE'
 flushCommits
                 Used to determine if the test should flush the table. Defau
lt: false
 writeToWAL
                 Set writeToWAL on puts. Default: True
```

<pre>autoFlush oneCon presplit sis (see</pre>	Set autoFlush on htable. Default: False all the threads share the same connection. Default: False Create presplit table. Recommended for accurate perf analy		
inmemory ble. Not	guide). Default: disabled Tries to keep the HFiles of the CF inmemory as far as possi		
	guaranteed that reads are always served from memory. Defa

                Run random write test
scan
                Run scan test (read every row)
scanRange10
                Run random seek scan with both start and stop row (max 10
rows)
                Run random seek scan with both start and stop row (max 100
scanRange100
rows)
scanRange1000
                Run random seek scan with both start and stop row (max 1000
rows)
scanRange10000 Run random seek scan with both start and stop row (max 1
0000 rows)
sequentialRead Run sequential read test
sequentialWrite Run sequential write test
Args:
nclients
                 Integer. Required. Total number of clients (and HRegionS
ervers)
                running: 1 <= value <= 500
Examples:
To run a single client doing the default 1M sequentialWrites:
 $ bin/hbase org.apache.hadoop.hbase.PerformanceEvaluation sequentialWrite 1
To run 10 clients doing increments over ten rows:
$ bin/hbase org.apache.hadoop.hbase.PerformanceEvaluation --rows=10 --noma
pred increment 10
```

#### LoadTestTool

The LoadTestTool utility load-tests your cluster by performing writes, updates, or reads on it. To run the LoadTest Tool, use the bin/hbase ltt command. To print general usage information, use the -h option.

```
$ bin/hbase ltt -h
Options:
 -batchupdate
                                 Whether to use batch as opposed to separate
updates for every column
                                 in a row
 -bloom <arg>
                                 Bloom filter type, one of [NONE, ROW, ROWC
OLl
 -compression <arg>
                                 Compression type, one of [LZO, GZ, NONE, SN
APPY, LZ4]
 -data_block_encoding <arg>
                                 Encoding algorithm (e.g. prefix compress
ion) to use for data blocks
                                 in the test column family, one of
                                 [NONE, PREFIX, DIFF, FAST_DIFF, PREFIX_T
REE].
 -deferredlogflush
                                 Enable deferred log flush.
 -encryption <arg>
                                 Enables transparent encryption on the test
table, one of [AES]
 -families <arg>
                                 The name of the column families to use se
parated by comma
 -generator <arg>
                                 The class which generates load for the too
1. Any args for this class
                                 can be passed as colon separated after c
lass name
 -h,--help
                                 Show usage
 -in_memory
                                 Tries to keep the HFiles of the CF inmemory
as far as possible.
                                 guaranteed that reads are always served fro
m inmemory
 -init_only
                                 Initialize the test table only, don't do
any loading
```

```
The 'key window' to maintain between reads
 -key_window <arg>
 and writes for concurrent
                                  write/read workload. The default is 0.
 -max_read_errors <arg>
                                  The maximum number of read errors to tol
erate before terminating all
                                  reader threads. The default is 10.
 -mob_threshold <arg>
                                 Desired cell size to exceed in bytes that
will use the MOB write path
 -multiget_batchsize <arg>
                                  Whether to use multi-gets as opposed to sep
arate gets for every
                                  column in a row
                                  Whether to use multi-puts as opposed to s
 -multiput
eparate puts for every
                                  column in a row
                                  The number of keys to read/write
 -num_keys <arg>
 -num_regions_per_server <arg>
                                 Desired number of regions per region serv
er. Defaults to 5.
                                 A positive integer number. When a number n
 -num_tables <arg>
 is specified, load test tool
                                 will load n table parallely. -tn parameter
value becomes table name prefix.
                                  Each table name is in format <tn>_1...<tn>
_n
                                  <verify_percent>[:<#threads=20>]
 -read <arg>
                                  The class for executing the read requests
 -reader <arg>
 -region_replica_id <arg>
                                  Region replica id to do the reads from
 -region_replication <arg>
                                 Desired number of replicas per region
 -regions_per_server <arg>
                                 A positive integer number. When a number n
 is specified, load test tool
                                  will create the test table with n regions p
er server
 -skip_init
                                  Skip the initialization; assume test table
 already exists
 -start_key <arg>
                                  The first key to read/write (a 0-based ind
ex). The default value is 0.
 -tn <arg>
                                  The name of the table to read or write
 -update <arg>
                                  <update_percent>[:<#threads=20>][:<#whether</pre>
 to ignore nonce collisions=0>]
                                  The class for executing the update requests
 -updater <arg>
 -write <arg>
                                  <avg cols per key>:<avg data size>[:<#thr</pre>
eads=20>]
                                  The class for executing the write requests
 -writer <arg>
 -zk <arg>
                                  ZK quorum as comma-separated host names w
ithout port numbers
 -zk_root <arg>
                                 name of parent znode in zookeeper
```

### wal

The wal utility prints information about the contents of a specified WAL file. To get a list of all WAL files, use the HDFS command hadoop fs -ls -R /hbase/WALs. To run the wal utility, use the bin/hbase wal command. Run it without options to get usage information.

#### hfile

The hfile utility prints diagnostic information about a specified hfile, such as block headers or statistics. To get a list of all hfiles, use the HDFS command hadoop fs -ls -R /hbase/data. To run the hfile utility, use the bin/hbase hf ilecommand. Run it without options to get usage information.

```
$ hbase hfile
usage: HFile [-a] [-b] [-e] [-f <arg> | -r <arg>] [-h] [-i] [-k] [-m] [-p]
      [-s] [-v] [-w < arg >]
-a,--checkfamily
                     Enable family check
-b,--printblocks
                         Print block index meta data
 -e,--printkey
                         Print keys
 -f,--file <arg>
                          File to scan. Pass full-path; e.g.
                         hdfs://a:9000/hbase/hbase:meta/12/34
 -h,--printblockheaders
                         Print block headers for each block.
                          Print all cells whose mob files are missing
 -i,--checkMobIntegrity
 -k,--checkrow
                          Enable row order check; looks for out-of-order
                          keys
-m,--printmeta
                          Print meta data of file
 -p,--printkv
                          Print key/value pairs
 -r,--region <arg>
                          Region to scan. Pass region name; e.g.
                          'hbase:meta,,1'
                          Print statistics
 -s,--stats
 -v,--verbose
                          Verbose output; emits file and meta data
                          delimiters
 -w,--seekToRow <arg>
                          Seek to this row and print all the kvs for this
                          row only
```

#### **hbck**

The hbck utility checks and optionally repairs errors in HFiles.

**Warning:** Running hbck with any of the -fix or -repair commands is dangerous and can lead to data loss. Contact Cloudera support before running it.

To run hbck, use the bin/hbase hbck command. Run it with the -h option to get more usage information.

```
NOTE: As of HBase version 2.0, the hbck tool is significantly changed.
In general, all Read-Only options are supported and can be be used
safely. Most -fix/ -repair options are NOT supported. Please see usage
below for details on which options are not supported.
Usage: fsck [opts] {only tables}
 where [opts] are:
   -help Display help options (this)
   -details Display full report of all regions.
   -timelag <timeInSeconds> Process only regions that have not experienced
 any metadata updates in the last <timeInSeconds> seconds.
   -sleepBeforeRerun <timeInSeconds> Sleep this many seconds before checking
 if the fix worked if run with -fix
   -summary Print only summary of the tables and status.
   -metaonly Only check the state of the hbase:meta table.
   -sidelineDir <hdfs://> HDFS path to backup existing meta.
   -boundaries Verify that regions boundaries are the same between META and
 store files.
   -exclusive Abort if another hbck is exclusive or fixing.
 Datafile Repair options: (expert features, use with caution!)
```

```
Check all Hfiles by opening them to make sure the
   -checkCorruptHFiles
y are valid
   -sidelineCorruptHFiles Quarantine corrupted HFiles. implies -checkCorru
ptHFiles
Replication options
   -fixReplication
                   Deletes replication queues for removed peers
 Metadata Repair options supported as of version 2.0: (expert features, use
 with caution!)
                   Try to fix missing hbase.version file in hdfs.
   -fixVersionFile
   -fixReferenceFiles Try to offline lingering reference store files
   -fixHFileLinks Try to offline lingering HFileLinks
   -noHdfsChecking Don't load/check region info from HDFS. Assumes hbas
e:meta region info is good. Won't check/fix any HDFS issue, e.g. hole, orpha
n, or overlap
   -ignorePreCheckPermission ignore filesystem permission pre-check
NOTE: Following options are NOT supported as of HBase version 2.0+.
  UNSUPPORTED Metadata Repair options: (expert features, use with caution!)
                     Try to fix region assignments. This is for backwards
   -fix
compatiblity
                     Try to fix region assignments. Replaces the old -fix
   -fixAssignments
                     Try to fix meta problems. This assumes HDFS region inf
   -fixMeta
o is good.
   -fixHdfsHoles
                     Try to fix region holes in hdfs.
   -fixHdfsOrphans
                     Try to fix region dirs with no .regioninfo file in hdfs
   -fixTableOrphans
                    Try to fix table dirs with no .tableinfo file in hdfs
 (online mode only)
   -fixHdfsOverlaps
                    Try to fix region overlaps in hdfs.
   -maxMerge <n>
                     When fixing region overlaps, allow at most <n> regions
 to merge. (n=5 by default)
   -sidelineBigOverlaps When fixing region overlaps, allow to sideline big
overlaps
   -maxOverlapsToSideline <n> When fixing region overlaps, allow at most <
n> regions to sideline per group. (n=2 by default)
   -fixSplitParents Try to force offline split parents to be online.
                     Try to offline and sideline lingering parents and keep
   -removeParents
 daughter regions.
   -fixEmptyMetaCells Try to fix hbase: meta entries not referencing any
region (empty REGIONINFO QUALIFIER rows)
  UNSUPPORTED Metadata Repair shortcuts
                     Shortcut for -fixAssignments -fixMeta -fixHdfsHoles -
   -repair
fixHdfsOrphans -fixHdfsOverlaps -fixVersionFile -sidelineBigOverlaps -fixRef
erenceFiles-fixHFileLinks
                     Shortcut for -fixAssignments -fixMeta -fixHdfsHoles
   -repairHoles
```

### clean

After you have finished using a test or proof-of-concept cluster, the hbase clean utility can remove all HBase-related data from ZooKeeper and HDFS.

**Warning:** The hbase clean command destroys data. Do not run it on production clusters, or unless you are absolutely sure you want to destroy the data.

To run the hbase clean utility, use the bin/hbase clean command. Run it with no options for usage information.

```
$ bin/hbase clean
Usage: hbase clean (--cleanZk|--cleanHdfs|--cleanAll)
Options:
```

Cloudera Runtime Use the Java API

```
--cleanZk cleans hbase related data from zookeeper.
--cleanHdfs cleans hbase related data from hdfs.
--cleanAll cleans hbase related data from both zookeeper and hdfs.
```

### **Use the Java API**

You can use the Apache HBase Java API to communicate with Apache HBase. The Java API is one of the most common ways to communicate with HBase.

The following sample uses Apache HBase APIs to create a table and put a row into that table. The table name, column family name, qualifier (or column) name, and a unique ID for the row are defined. Together, these define a specific cell. Next, the table is created and the text "Hello, World!" is inserted into this cell.

```
import java.io.IOException;
import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.hbase.HBaseConfiguration;
import org.apache.hadoop.hbase.TableName;
import org.apache.hadoop.hbase.client.*;
import org.apache.hadoop.hbase.util.Bytes;
public class CreateAndPut {
   private static final TableName TABLE_NAME = TableName.valueOf("test_tabl
e_example");
   private static final byte[] CF_NAME = Bytes.toBytes("test_cf");
   private static final byte[] QUALIFIER = Bytes.toBytes("test_column");
   private static final byte[] ROW_ID = Bytes.toBytes("row01");
   public static void createTable(final Admin admin) throws IOException {
        if(!admin.tableExists(TABLE_NAME)) {
            TableDescriptor desc = TableDescriptorBuilder.newBuilder(TABLE_
NAME)
                    .setColumnFamily(ColumnFamilyDescriptorBuilder.of(CF_N
AME))
                    .build();
            admin.createTable(desc);
        }
   public static void putRow(final Table table) throws IOException {
        table.put(new Put(ROW_ID).addColumn(CF_NAME, QUALIFIER, Bytes.toByte
s("Hello, World!")));
   public static void main(String[] args) throws IOException {
        Configuration config = HBaseConfiguration.create();
        try (Connection connection = ConnectionFactory.createConnection(co
nfig); Admin admin = connection.getAdmin()) {
            createTable(admin);
            try(Table table = connection.getTable(TABLE_NAME)) {
                putRow(table);
        }
```

# **Use the Apache Thrift Proxy API**

The Apache Thrift library provides cross-language client-server remote procedure calls (RPCs), using *Thrift bindings*.

### Prepare Thrift server and client before using Thrift Proxy API

A *Thrift binding* is client code generated by the Apache Thrift Compiler for a target language (such as Python) that allows communication between the Thrift server and clients using that client code. HBase includes an Apache Thrift Proxy API, which allows you to write HBase applications in Python, C, C++, or another language that Thrift supports. The Thrift Proxy API is slower than the Java API and may have fewer features. To use the Thrift Proxy API, you need to configure and run the HBase Thrift server on your cluster. You also need to install the Apache Thrift compiler on your development system.

After the Thrift server is configured and running, generate *Thrift bindings* for the language of your choice, using an IDL file. An HBase IDL file named HBase.thrift is included as part of HBase. After generating the bindings, copy the Thrift libraries for your language into the same directory as the generated bindings. In the following Python example, these libraries provide the thrift.transport and thrift.protocol libraries. These commands show how you might generate the *Thrift bindings* for Python and copy the libraries on a Linux system.

After installation of the thrift compiler, verify that the thrift compiler version is newer than 0.9.0 by running the thrift -version command. You need to find the Hbase.thrift file from the HBase node or copy it to co-locate with the Thrift compiler. Perform the following steps:

```
mkdir HBaseThrift
cd HBaseThrift/
thrift -gen py /path/to/Hbase.thrift
mv gen-py/* .
rm -rf gen-py/
mkdir thrift
cp -rp ~/Downloads/thrift/lib/py/src/* ./thrift/
```

As a result, the HBase thrift Python bindings appears as follows:

```
HbaseThrift/
 -- hbased
     -- constants.py
     -- Hbase.py
     -- Hbase-remote
     -- __init__.py
     -- ttypes.py
     _init__.py
    thrift
     -- compat.py
     -- ext
         -- binary.cpp
         -- binary.h
         -- compact.cpp
         -- compact.h
         -- endian.h
         -- module.cpp
         -- protocol.h
         -- protocol.tcc
         -- types.cpp
          -- types.h
         _init__.py
        protocol
         -- __init__.py
         -- TBase.py
         -- TBinaryProtocol.py
```

```
-- TCompactProtocol.py
    -- THeaderProtocol.py
   -- TJSONProtocol.py
   -- TMultiplexedProtocol.py
   -- TProtocolDecorator.py
   -- TProtocol.py
-- server
        _init__.py
   -- THttpServer.py
   -- TNonblockingServer.py
   -- TProcessPoolServer.py
   -- TServer.py
-- Thrift.py
-- TMultiplexedProcessor.py
-- transport
   -- __init__.py
   -- sslcompat.py
   -- THeaderTransport.py
   -- THttpClient.py
   -- TSocket.py
   -- TSSLSocket.py
   -- TTransport.py
   -- TTwisted.py
   `-- TZlibTransport.py
-- TRecursive.py
-- TSCons.py
-- TSerialization.py
-- TTornado.py
```

### Introduction to example codes

Choose the right class and functions along with the right configurations for HBase.

### **Classes and functions**

- Transport level: TBufferedTransport, TFramedTransport, TSaslTransport, and THttpClient.
- Protocol level: TBinaryProtocol and TCompactProtocol.

### Configurations for HBase thrift

HBase thrift configurations

Property	Default value (secured)	Default value (unsecured)	Description
hbase.thrift.support.proxyuser	true	true	Use this to allow proxy users on the thrift gateway, which is mainly needed for doAs functionality.
hbase.regionserver.thrift.framed	true	true	Use framed transport. When using the THsHaServer or TNonblockingServer, framed transport is always used irrespective of this configuration value.
hbase.regionserver.thrift.compact	true	true	Use the TCompactProtocol instead of the default TBinaryProtocol. TCompactProtocol is a binary protocol that is more compact than the default and typically more efficient.
hbase.regionserver.thrift.http	true	true	Use this to enable HTTP server usage on thrift, which is mainly needed for doAs functionality.

Property	Default value (secured)	Default value (unsecured)	Description
hbase.thrift.security.qop	auth_conf	none	If this is set, HBase Thrift Server authenticates its clients. HBase Proxy User Hosts and Groups must be configured to allow specific users to access HBase through Thrift Server.
hbase.thrift.ssl.enabled	true	false	Encrypt communication between clients and HBase Thrift Server over HTTP using Transport Layer Security (TLS) (formerly known as Secure Socket Layer (SSL)).

### **Example-1 THttpClient in Secure Cluster**

Let us consider that the cluster is secured with the configuration properties mentioned in the *HBase thrift* configurations table under the *Default value (secured)* column.

Before proceeding, ensure that the following applications are installed on your system.

- python 3.6.8 and python 3-devel
- pip 21.3.1
- virtualenv 20.17.1

Perform the following steps:

1. Install virtualenv using pip3.

```
pip3 install virtualenv
```

2. Create a new virtual environment named PY3ENV.

```
virtualenv py3env
```

**3.** Activate the virtual environment.

```
source py3env/bin/activate
```

**4.** Install the required Python packages and their specific versions. Consider you are inside the python3 virtual environment.

```
pip3 install kerberos==1.3.1 pure-sasl==0.6.2 setuptools==59.6.0 six==1.
16.0 wheel==0.37.1
```

This ensures that you have all the necessary dependencies and packages installed to proceed with your project.

```
from thrift.transport import THttpClient
from thrift.protocol import TBinaryProtocol
from hbase.Hbase import Client
from subprocess import call
import ssl
import kerberos
import os

# Get the env parameters
def get_env_params():
    # Replace with your own parameters
    hostname='your_hbase_thrift_hostname'
    cert_file="your_cert_file"
    key_file="your_key_file"
    ca_file="your_key_file"
    key_pw='your_key_pw'
```

```
keytab_file='your_keytab'
   principal = 'your_principal'
   return hostname,cert_file,key_file,ca_file,keytab_file,principal,key_pw
#Check if a valid Kerberos ticket is already present in the cache
def check_kerberos_ticket():
    ccache_file = os.getenv('KRB5CCNAME')
    if ccache_file:
        ccache = CCache.load_ccache(ccache_file)
        if ccache.get_principal() and not ccache.get_principal().is_anonymou
s():
            return True
   return False
# Obtain a Kerberos ticket by running kinit from keytab
def kinit(keytab_file,principal):
    call(['kinit', '-kt', keytab_file, principal])
# Authenticate with Kerberos
def kerberos_auth():
     _, krb_context = kerberos.authGSSClientInit("HTTP")
   kerberos.authGSSClientStep(krb_context, "")
   negotiate_details = kerberos.authGSSClientResponse(krb_context)
   headers = {'Authorization': 'Negotiate ' + negotiate_details, 'Content-T
ype': 'application/binary'}
   return headers
# Initializete an SSL context with certificate verification enabled
def get_ssl_context():
    ssl_context = ssl.create_default_context()
    ssl_context.load_cert_chain(certfile=cert_file,keyfile=key_file,passwo
rd=key_pw)
    ssl_context.load_verify_locations(cafile=ca_file)
   return ssl_context
    __name___ == '___main_
   hostname, cert_file, key_file, ca_file, keytab_file, principal, key_pw=get_env
_params()
    # Check if a valid Kerberos ticket is not in the cache, then kinit.
    if not check_kerberos_ticket():
        kinit(keytab_file,principal)
# create a THttpClient instance with the SSL context and custom headers
   httpClient = THttpClient.THttpClient('https://' + hostname + ':9090/', s
sl_context=get_ssl_context())
   httpClient.setCustomHeaders(headers=kerberos_auth())
# Initialize TBinaryProtocol with THttpClient
   protocol = TBinaryProtocol.TBinaryProtocol(httpClient)
# Create HBase client
    client = Client(protocol)
# Retrieve list of HBase tables
    tables = client.getTableNames()
    print(tables)
# Close connection
   httpClient.close()
```

### **Example-2 THttpClient in Unsecure Cluster**

Let us consider that the cluster is unsecured with the configuration properties mentioned in the *HBase thrift* configurations table under the *Default value (unsecured)* column.

```
from thrift.transport import THttpClient
```

```
from thrift.protocol import TBinaryProtocol
from hbase.Hbase import Client
# Replace with your own parameters
hostname = 'your_hbase_thrift_server_hostname'

# Initialize THttpClient
httpClient = THttpClient.THttpClient('http://' + hostname + ':9090/')

# Initialize TBinaryProtocol with THttpClient
protocol = TBinaryProtocol.TBinaryProtocol(httpClient)

# Create HBase client
client = Client(protocol)

# Retrieve list of HBase tables
tables = client.getTableNames()
print(tables)

# Close connection
httpClient.close()
```

### Example-3 TSasIClientTransport in Secure Cluster without HTTP

If you do not use THttpClient and want to use TSaslClientTransport for legacy compatibility reasons, ensure that you set hbase.regionserver.thrift.http property to false. The other settings could be same as the configuration properties mentioned in the *HBase thrift configurations* table under the *Default value (secured)* column.

```
from thrift.transport import TSocket
from thrift.transport import TTransport
from thrift.protocol import TBinaryProtocol
from thrift.protocol import TCompactProtocol
from hbase import Hbase
Assume you already kinit the hbase principal, or you can use the function
in example-1 to kinit.
# Replace with your own parameters
thrift_host = 'your_hbase_thrift_server_hostname'
thrift_port = 9090
# Initialize TSocket and TTransport
socket = TSocket.TSocket(thrift_host, thrift_port)
transport=TTransport.TSaslClientTransport(socket,host=thrift_host,service='
hbase', mechanism='GSSAPI')
# Initialize TCompactProtocol with TTransport
protocol = TCompactProtocol.TCompactProtocol(transport)
# Create HBase client
client = Hbase.Client(protocol)
# Open connection and retrieve list of HBase tables
transport.open()
tables = client.getTableNames()
print(tables)
# Close connection
transport.close()
```

Cloudera recommends you to use the HTTP options (Example-1 and Example-2). You can consider the Example-3 for legacy compatibility issues where some old applications might not rewrite the codes. This is because Hue is using

Cloudera Runtime

Use the Hue HBase app

HTTP mode to interact with HBase thrift, and if you disable the HTTP mode, Hue might not work properly with HBase.

### Known bugs while using TSaslClientTransport with Kerberos enabled CDP versions

Upstream JIRA HBASE-21652, where a bug is introduced related to Kerberos principal handling. The affected versions are CDP 7.1.6 and earlier. The versions containing the fix are 7.1.7, 7.2.11, and later.

Python interaction with HBase Thrift proxy in Secured Cluster

Apache Thrift document

# Use the Hue HBase app

Hue is a web-based interactive query editor that enables you to interact with data warehouses. You can use the HBase Browser application in Hue to create and browse HBase tables.

The HBase Hue app enables you to insert a new row or bulk upload CSV files, TSV files, and type data into your table. You can also insert columns into your row. If you need more control or data about your cell, you can use the full editor to edit a cell.

If you are using the HBase Thrift interface, Hue fits in between the Thrift Server and the HBase client, and the Thrift Server assumes that all HBase operations come from the hue user and not the client. To ensure that users in Hue are only allowed to perform HBase operations assigned to their own credentials, and not those of the hue user, you must enable doAs Impersonation for the HBase Browser Application.
